Z is the **partition function**.

Two Periodic Weighting

The **two-periodic weighting** of the Aztec diamond is defined in the following way. For a two-colouring of the faces, the edge weights around a particular coloured face alternate between a and b, we have a-edges and b-edges. E.g. for a size 4 Aztec diamond

Random tiling of a two-periodic Aztec diamond

Aztec diamond height function

To each tiling of an Aztec diamond we can associate a **height function**. The heights sit on the faces of the Aztec graph. The height differences between two faces are given by

- +3(-3) if we cross a dimer with a white vertex to the right (left)
- +1 (-1) if we do not cross a dimer and have a white vertex to the left (right)

Kasteleyn Matrix

We choose a **Kasteleyn sign**, s(e), |s(e)| = 1, for each edge with certain properties, and then define the **Kasteleyn matrix** \mathbb{K} with elements

$$\mathbb{K}(b_i, w_j) = s(b_i, w_j)\nu(b_i, w_j).$$

This is a signed weighted adjacency matrix for the graph. For the Aztec diamond graph we can take

$$\mathbb{K}(b,w) = \begin{cases} \nu(bw) & \text{if } e = (b,w) \text{ is horizontal} \\ i\nu(bw) & \text{if } e = (b,w) \text{ is vertical} \\ 0 & \text{otherwise (i.e. no edge between } b \text{ and } w) \end{cases}$$

Kasteleyn's theorem

Let \mathbb{K} be a Kasteleyn matrix Theorem (Kasteleyn)

 $\det(\mathbb{K}) = SZ,$

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

where Z is the partition function, and |S| = 1.

Kasteleyn's theorem

Let \mathbb{K} be a Kasteleyn matrix Theorem (Kasteleyn)

 $\det(\mathbb{K}) = SZ,$

where Z is the partition function, and |S| = 1. It follows from Kasteleyn's theorem that

Theorem (Montroll-Potts-Ward, Kenyon) If $e_i = (b_i, w_i)$, then the probability that e_1, \ldots, e_m belong to a dimer cover is

$$\mathbb{P}(e_1,\ldots,e_m) = \det \left(\mathbb{K}(b_i,w_i) \mathbb{K}^{-1}(w_i,b_j) \right)_{1 \le i,j \le m}$$

This means that the dimers form a **determinantal point process** with correlation kernel $K(e_i, e_j) = \mathbb{K}(b_i, w_i)\mathbb{K}^{-1}(w_i, b_j), e_i = (b_i, w_i)$.

Phases

The curve in the picture is a degree 8 curve with two real components. We get three regions which are called **frozen, rough and smooth**.

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

Kenyon, Okounkov and Sheffield have characterized the different **limiting translation invariant Gibbs measures** that are possible for bipartite dimer models on the plane.

There are three classes of Gibbs measures, **frozen**, **rough** and **smooth**, given by an appropriate infinite, translation-invariant full-plane inverse Kasteleyn matrix \mathbb{K}^{-1} .

Kenyon, Okounkov and Sheffield have characterized the different **limiting translation invariant Gibbs measures** that are possible for bipartite dimer models on the plane.

There are three classes of Gibbs measures, **frozen**, **rough** and **smooth**, given by an appropriate infinite, translation-invariant full-plane inverse Kasteleyn matrix \mathbb{K}^{-1} .

Correlations between dominos decay polynomially with distance in the rough region, and exponentially in the smooth region.

Rough-smooth boundary

We now have two types of boundaries, the rough-frozen boundary and the rough-smooth boundary.

Rough-smooth boundary

What can we say about the interface fluctuations at the rough-smooth boundary? What is actually the interface?

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Rough-smooth boundary

What can we say about the interface fluctuations at the rough-smooth boundary? What is actually the interface?

The rough-frozen interface is well-defined, the first place when the regular pattern is broken

At the rough-smooth boundary the situation is less clear. How should we define the interface combinatorially at the discrete level?

Formula for the inverse Kasteleyn matrix in the two-periodic case

▲□▶ ▲圖▶ ★ 国▶ ★ 国▶ - 国 - のへで

The coordinate system that we use is indicated in the figure.

Theorem (Chhita-J. based on Chhita-Young)

Consider an Aztec diamond of size n = 4m with the two-periodic weighting and let \mathbb{K}_m be its Kasteleyn matrix. Then,

$$\mathbb{K}_m^{-1}((x_1, x_2), (y_1, y_2)) = \mathbb{K}_{sm}^{-1}((x_1, x_2), (y_1, y_2)) - \sum_{i=1}^4 B_i((x_1, x_2), (y_1, y_2)),$$

where \mathbb{K}_{sm}^{-1} is the full-plane inverse Kasteleyn matrix for the smooth phase, which has an explicit double integral formula, and B_1, \ldots, B_4 are contributions also given by explicit double integral formulas.

The inverse Kasteleyn Matrix

Theorem (Chhita-J. based on Chhita-Young)

Consider an Aztec diamond of size n = 4m with the two-periodic weighting and let \mathbb{K}_m be its Kasteleyn matrix. Then,

$$\mathbb{K}_m^{-1}((x_1, x_2), (y_1, y_2)) = \mathbb{K}_{sm}^{-1}((x_1, x_2), (y_1, y_2)) - \sum_{i=1}^4 B_i((x_1, x_2), (y_1, y_2)),$$

where \mathbb{K}_{sm}^{-1} is the full-plane inverse Kasteleyn matrix for the smooth phase, which has an explicit double integral formula, and B_1, \ldots, B_4 are contributions also given by explicit double integral formulas.

Recently a more systematic approach has been developed to get the inverse Kasteleyn matrix or, more specifically, a closely related correlation kernel for an associated particle process, see *The two periodic Aztec diamond and matrix valued orthogonal polynomials*, by Maurice Duits, Arno B.J. Kuijlaars and *Correlation functions for determinantal processes defined by infinite block Toeplitz minors*, by T. Berggren, M. Duits.

Airy kernel point process

Figure: The Airy line ensemble. The top path is the Airy process.

▲□▶ ▲圖▶ ★ 国▶ ★ 国▶ - 国 - のへで

Airy kernel point process

The extended Airy point process is a determinantal point process on parallel lines $\{\tau_q\} \times \mathbb{R}$, $1 \le q \le L_1$ in \mathbb{R}^2 . We can think of it as a random measure μ_{Ai} defined via a Laplace transform. Let A_p , $1 \le p \le L_2$, be disjoint intervals in \mathbb{R} , $w_{p,q} \in \mathbb{C}$,

$$\mathbb{E}\bigg[\exp\bigg(\sum_{p=1}^{L_2}\sum_{q=1}^{L_1} w_{p,q}\mu_{\mathsf{A}\mathsf{i}}(\{\tau_q\}\times A_p)\bigg)\bigg]$$

= det $\big(I + (e^{\Psi} - 1)K_{\mathsf{ext}\mathsf{A}\mathsf{i}}\big)_{L^2(\{\tau_1,\dots,\tau_q\}\times\mathbb{R})}$

where

$$\Psi(x) = \sum_{q=1}^{L_1} \sum_{p=1}^{L_2} w_{p,q} \mathbb{I}_{\{\tau_q\} \times A_p}(x).$$

Airy kernel point process

$$\mathbb{E}\left[\exp\left(\sum_{p=1}^{L_2}\sum_{q=1}^{L_1}w_{p,q}\mu_{\mathsf{A}\mathsf{i}}\left(\{\tau_q\}\times A_p\right)\right)\right]$$

= det $\left(I + (e^{\Psi} - 1)\mathcal{K}_{\mathsf{ext}\mathsf{A}\mathsf{i}}\right)_{L^2(\{\tau_1,\dots,\tau_q\}\times\mathbb{R})},$

where

$$\Psi(x)=\sum_{q=1}^{L_1}\sum_{p=1}^{L_2}w_{p,q}\mathbb{I}_{\{\tau_q\}\times A_p}(x).$$

Recall that the extended Airy kernel is given by

$$K_{\text{extAi}}(\tau_1,\xi_1;\tau_2,\xi_2) = -\phi_{\tau_1,\tau_2}(\xi_1,\xi_2) + \tilde{K}_{\text{extAi}}(\tau_1,\xi_1;\tau_2,\xi_2),$$

where

$$\tilde{\mathcal{K}}_{\text{extAi}}(\tau_1,\xi_1;\tau_2,\xi_2) = \int_0^\infty e^{-\lambda(\tau_1-\tau_2)} \operatorname{Ai}\left(\xi_1+\lambda\right) \operatorname{Ai}\left(\xi_2+\lambda\right) d\lambda.$$

Asymptotics for the inverse Kasteleyn matrix at the rough-smooth boundary

Let $x = (x_1, x_2)$ be a white vertex and $y = (y_1, y_2)$ a black vertex. Scaling around a point at the rough-smooth boundary:

$$\begin{aligned} (x_1, x_2) &= (4[\rho m] + 2[c_1\xi_1 m^{1/3}](1, 1) - 2[c_2\tau_1 m^{2/3}](-1, 1), \\ (y_1, y_2) &= (4[\rho m] + 2[c_1\xi_2 m^{1/3}](1, 1) - 2[c_2\tau_2 m^{2/3}](-1, 1). \end{aligned}$$

Random measure from the height function

▲□> <圖> < E> < E> E のQQ

Random measure from the height function

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

Height differences between two points in a vicinity of the rough-smooth boundary are due to two effects:

- Small and basically independent height fluctuations due to the "surrounding smooth phase".
- Long distance correlated effects due to the large scale structures that we see in the figure.
- By taking suitable averages of height differences we could hope to eliminate the small scale smooth phase effects. This is the idea behind the definition of a certain random signed measure.

→ 圖 → → 注 → → 注 → → 注

Consider a two-periodic Aztec diamond of size n = 4m.

We want to imbed the intervals A_p as discrete intervals of length $\sim m^{1/3}$ in the Aztec diamond at the rough-smooth boundary. Consider only one interval, $A = [a', a^r]$. We want to imbed $M = [(\log m)^4]$ copies of it as discrete intervals starting and ending at a-faces a certain distance apart.

・ロト ・ 理 ト ・ ヨ ト ・ ヨ ト ・ ヨ

The height change along a discrete interval

 $\Delta h(I) = h(F_{+}(I)) - h(F_{-}(I)).$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへで

Random signed measure

$$\mu_m(\{\beta\}\times A)=\frac{1}{4M}\sum_{k=1}^M\Delta h(I_k).$$

Theorem (Beffara, Chhita, J., 18)

The random signed measure μ_m converges to μ_{Ai} .

For one interval the result is

$$\lim_{m\to\infty}\mathbb{E}\big[e^{w\mu_m(A)}\big]=\mathbb{E}\big[e^{w\mu_{Ai}(A)}\big],$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

for $w \in \mathbb{C}$, |w| < R.

Squishing

An *a*-dimer is a dimer that covers an *a*-edge. They are **oriented** from white to black.

Figure: The red dimers are *a*-dimers, and the black *b*-dimers.

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

Squishing

We let the *b*-faces become smaller, go to zero in size.

Squishing

We get double edges, loops and paths.

Paths and Loops

To get a unique split between paths and loops and get well-defined loops we need a convention. We use **mirrors**.

▲ロト ▲帰 ト ▲ ヨ ト ▲ ヨ ト ・ ヨ ・ の Q ()

Paths

The paths go between the boundaries.

Figure: After squishing.

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Paths

The paths go between the boundaries.

Figure: After squishing, n = 300, a = 0.5.

What we would like to prove

With high probability, if we go along the main diagonal there is a last path in the third quadrant close to the asymptotic rough-smooth boundary and this path converges to the Airy process.

What we can prove

Let h(f) be the height at the *a*-face f in the Aztec diamond. Then we can split it into two parts:

$$h(f) = h_{\ell}(f) + h_{c}(f)$$

where $h_{\ell}(f)$ is the **loop height** and $h_{c}(f)$ is the **corridor height**.

・ロト・日本・モート モー うへぐ

What we can prove

Assume that a < 1/3. Imbed the interval A as a discrete interval of length $\sim m^{1/3}$ in the Aztec diamond at the rough-smooth boundary. Define the **new random signed measure**

$$\kappa_m(\{\beta\}\times A)=\frac{1}{4}(h_c(F_+)-h_c(F_-)),$$

where F_+ and F_- are the end-faces of the discrete imbedded interval. Then $\kappa_m(\{\beta\} \times A)$ converges weakly to $\mu_{Ai}(\{\beta\} \times A)$ as $m \to \infty$, where μ_{Ai} is the Airy kernel point process.

We expect that with high probability κ_m is actually a positive measure. We should think of κ_m as counting the number of paths between the two faces.

Ingredients in the proof

- Show that the averaging in the random signed measure μ_m can be done along a single line instead of on parallel lines.
- We control the size of the loops; in a box of size L they are no bigger than C log L. This uses a Peierls' type argument and requires a < 1/3.

- In a not too large region at the rough-smooth boundary the two-periodic Aztec measure can be replaced by the full-plane smooth measure.
- There are no bi-infinite paths in the full-plane smooth phase.

Thank you for listening!
