# Co-degree for *r*-graphs

An *r*-graph is an *r*-uniform hypergraph.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

An *r*-graph is an *r*-uniform hypergraph.

In an *r*-graph, the *co-degree* of a set *S* of r - 1 vertices, denoted  $d_{r-1}(S)$ , is the number of *r*-edges which contain *S*.

An *r*-graph is an *r*-uniform hypergraph.

In an *r*-graph, the *co-degree* of a set *S* of r - 1 vertices, denoted  $d_{r-1}(S)$ , is the number of *r*-edges which contain *S*.

For an r-graph H, the minimum co-degree of H is

$$\delta_{r-1}(H) = \min\{d_{r-1}(S) : S \subset V(H), |S| = r-1\}.$$

An *r*-graph is an *r*-uniform hypergraph, *i.e.*, a set system in which all sets have size r.

In an *r*-graph, the *co-degree* of a set *S* of r - 1 vertices, denoted  $d_{r-1}(S)$ , is the number of *r*-edges which contain *S*.

For an r-graph H, the minimum positive co-degree of H is

$$\delta^+_{r-1}(H) = \min\{d_{r-1}(S) : S \subset V(H), |S| = r-1, d_{r-1}(S) > 0\}.$$

Let F be a fixed r-graph. Let  $S_n$  be the set of n-vertex, F-free r graphs. We define

$$coex(n, F) := max\{\delta_{r-1}(H) : H \in S_n\}$$

and

$$co^+ex(n,F) := \max\{\delta^+_{r-1}(H) : H \in \mathcal{S}_n\}.$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

Let F be a fixed r-graph. Let  $S_n$  be the set of n-vertex, F-free r graphs. We define

$$coex(n, F) := max\{\delta_{r-1}(H) : H \in S_n\}$$

and

$$co^+ex(n,F) := \max\{\delta^+_{r-1}(H) : H \in \mathcal{S}_n\}.$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

The study of coex(n, F) is well established;  $co^+ex(n, F)$  is a natural related question recently introduced.

#### Let $K_4^-$ be the 3-graph on 4 vertices and 3 3-edges.

(ロ)、(型)、(E)、(E)、 E) の(()

٠

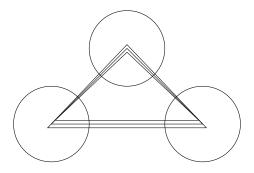

Let  $K_4^-$  be the 3-graph on 4 vertices and 3 3-edges.

H., Lemons, and Palmer showed that

$$co^+ex(n, K_4^-) = \lfloor n/3 \rfloor$$

(ロ)、(型)、(E)、(E)、 E) の(()

Consider the balanced blow-up of a single 3-edge:

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

Let  $H_6$  be the 3-graph arising from the unique (6,3,2)-design. We can check that any blow-up of  $H_6$  is  $K_4^-$ -free.

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Let  $H_6$  be the 3-graph arising from the unique (6,3,2)-design. We can check that any blow-up of  $H_6$  is  $K_4^-$ -free.

It is also true that when  $n \equiv 0 \mod 6$ , the balanced *n*-vertex blow-up of  $H_6$  has minimum positive co-degree n/3.

Theorem (H.- Lemons- Palmer, 2022+)

$$co^+ex(n, K_4^-) = \lfloor n/3 \rfloor.$$

Moreover, suppose *H* achieves  $co^+ex(n, K_4^-)$ . If  $n \equiv 3 \mod 6$ , then *H* is the balanced blow-up of a 3-edge. If  $n \equiv 0 \mod 6$ , then *H* is either the balanced blow-up of a 3-edge or the balanced blow-up of *H*<sub>6</sub>.

Theorem (H.- Lemons- Palmer, 2022+)

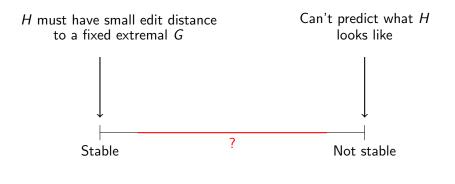

$$co^+ex(n, K_4^-) = \lfloor n/3 \rfloor.$$

Moreover, suppose *H* achieves  $co^+ex(n, K_4^-)$ . If  $n \equiv 3 \mod 6$ , then *H* is the balanced blow-up of a 3-edge. If  $n \equiv 0 \mod 6$ , then *H* is either the balanced blow-up of a 3-edge or the balanced blow-up of *H*<sub>6</sub>.

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

Is this behavior interesting?

H is near extremal

◆□ > ◆□ > ◆豆 > ◆豆 > ̄豆 = のへで

Idea: when there are multiple extremal constructions (with big edit distance), then we won't have "normal" stability.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Idea: when there are multiple extremal constructions (with big edit distance), then we won't have "normal" stability.

If we can find t distinct constructions so that any near-extremal r-graph has small edit distance from one, we say our problem is t-stable

A general notion of *t*-stability was recently introduced by Mubayi for extremal questions where the goal is to maximize the number of (hyper)edges.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

A general notion of *t*-stability was recently introduced by Mubayi for extremal questions where the goal is to maximize the number of (hyper)edges.

"Ordinary" stability is often seen in classical Turán theory. Some extremal set theory questions (e.g., finding large intersecting families) have no stability.

A general notion of t-stability was recently introduced by Mubayi for extremal questions where the goal is to maximize the number of (hyper)edges.

"Ordinary" stability is often seen in classical Turán theory. Some extremal set theory questions (e.g., finding large intersecting families) have no stability.

*t*-stability results for t > 1 are less common. Liu and Mubayi recently found the first hypergraph Turán problem with 2-stability.

### Theorem (Garcia-H.)

Let *H* be an *n*-vertex,  $K_4^-$ -free 3-graph with

$$\delta_2^+(H)=n/3-o(n).$$

Then *H* has edit distance  $o(n^3)$  from either the *n*-vertex balanced blow-up of a 3-edge or the *n*-vertex balanced blow-up of  $H_6$ .

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

- Identify a "special" vertex v of H and look at the link graph L(v);
- Argue that, because v is special, we can transform L(v) into one of two forms with few edits;
- Argue that, if L(v) is of a good form, then we need only few edits to change to an extremal construction

#### Theorem (Frankl-Füredi, 1984)

Let *H* be an *n*-vertex 3-graph in which any four vertices span either 0 or 2 3-edges. Then *H* is either isomorphic to a blow-up of  $H_6$ , or to a 3-graph obtained by placing *n* points on the unit circle, with edges corresponding to triangles containing the origin.

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

Inspired by the Frankl-Füredi theorem, we will let b(v) be the number of 4-sets of vertices which contain v and span exactly 1 edge.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Inspired by the Frankl-Füredi theorem, we will let b(v) be the number of 4-sets of vertices which contain v and span exactly 1 edge.

Because  $\delta_2^+(H) > n/3 - o(n)$ , it is quick to check that some v has  $b(v) = o(n^4)$ . This is our "special" vertex.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

The link graph L(v) is the 2-graph on vertex set  $V(H) \setminus \{v\}$  where *xy* is an edge if *xyv* is a 3-edge of *H*.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

The link graph L(v) is the 2-graph on vertex set  $V(H) \setminus \{v\}$  where xy is an edge if xyv is a 3-edge of H.

Certain subgraphs of L(v) indicate bad sets containing v in H. Since v is special, we can indicate that we don't see too many of these "bad" subgraphs.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

After some work...

After some work...

With  $o(n^3)$  edits, we can transform so that the link graph L(v) is either bipartite or a subgraph of a  $C_5$  blow-up.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

After some work...

With  $o(n^3)$  edits, we can transform so that the link graph L(v) is either bipartite or a subgraph of a  $C_5$  blow-up.

We can also show that these edits maintain the "specialness" of v.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

The link graph will naturally partition the vertices of H into different classes, and says where the 3-edges involving v live.

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ □臣 ○のへ⊙

The link graph will naturally partition the vertices of H into different classes, and says where the 3-edges involving v live.

Last step: edges not involving v also must go where we expect. (Similar work to showing that the link graph looks nice.)
